The road to successful CRT implantation: The role of echo

Tae-Ho Park

Dong-A University Hospital, Busan, Korea
Terminology

- Cardiac Resynchronization Therapy (CRT)
  = Biventricular pacing (BiV)
  = Left ventricular pacing (LV)
  ≠ Dual chamber pacing

- Dyssynchrony
  = Asynchrony
First developed

- 1960, Pacemaker (Chardack, Wilson, Greatbach)
- 1966, ICD (Mirowski)
- 1983 CRT first report (De Teresa PA, et al) VIIth World Symposium of Cardiac Pacing 1983
What is CRT?

Patient:
- CHF
- LV systolic dysfunction
- Mechanical dyssynchrony

Ventricular pre-activation to improve mechanical synchrony
Indication of CRT

• NYHA class III/IV

• LVEF $\leq 35\%$

• QRS $\geq 120-130$ ms

Usual study enroll criteria
2005 ACC/AHA guideline
Wide QRS

- **Simple marker** of mechanical dyssynchrony
- Oversimplification
Clinical benefit of CRT

- Symptoms
- Mortality
Symptoms

- MUSTIC (2002 JACC): NYHA 25% ↓
- CARE-HF (2005 NEJM): NYHA 0.6↓
Mortality

Cardiac Resynchronization and Death From Progressive Heart Failure
A Meta-analysis of Randomized Controlled Trials

51% reduction (in progressive HF) (2003 JAMA)

Cardiac-Resynchronization Therapy
with or without an Implantable Defibrillator
in Advanced Chronic Heart Failure

24% reduction (death any cause) (2003 NEJM)

COMPANION (Comparison of Medical Therapy, Pacing, and Defibrillation in the Heart Failure)
Mortality

36% RRR (20% vs. 30% death)

CARE-HF, 2005 NEJM
CRT response

Clinical Versus Echocardiographic Parameters to Assess Response to Cardiac Resynchronization Therapy

Definition of responder

NYHA decreased $\geq 1$
EF improvd $\geq 5$
LVEDV dcreased $\geq 15$

Am J Cardiol 2006;97:260-3
Echo in CRT

- Patients selection (Symptom, ECG, EF)
- Evaluation of dessynchrony (important of CRT response)

Am J Cardiol 2006;97:260-3
Dyssynchrony

• Definition: incorordination in cardiac contraction and relaxation

• 3 types
  Atrioventricular dyssynchrony
  Interventricular dyssynchrony
  Intra-(LV) dyssynchrony
Dyssynchrony

- Typically early septal contraction, followed by late posterior-lateral contraction
- Dyssynchrony results in inefficient LV systolic performance, increases in end-systolic volume and wall stress, and delayed relaxation
Goal of Echo (imaging)

- Wide QRS without mechanical dyssynchrony
Mechanical dyssynchrony

• Difficult
• No single ideal index exists
(1) Inter-ventricular dyssynchrony

Most evidence suggests that interventricular dyssynchrony is not useful in the prediction of response of CRT

JASE 2008;21:191-213

2004 JACC
(6) 12 segments methods

- Maximal difference in the time to peak systolic velocity among all segments, where a cut-off value of greater than or equal to 100 milliseconds predicts response to CRT.

Yu CM et al 2004 Circulation
(7) Yu-index

• Standard deviation of Ts of the 12 LV segments (Ts-SD)

Ts-SD 31.4 ms
Sensitivity 96%
Specificity 78%

Yu CM et al 2004 Circulation
(8) TDI Strain

- Longitudinal strain is calculated linearly from TD velocity data as percent shortening.
- This enables differentiation between passive wall motion and true contraction and theoretically should more accurately identify dyssynchrony.

Before CRT
TDI Strain

- Low signal-to-noise ratio is believed to be the explanation for its poor reproducibility independent of the operator's experience.
- PSS, SRI were not able to predict of reverse remodelling.

Yu CM et al 2004 Circulation
(9) Speckle tracking strain

- A more recent approach is application of a speckle-tracking program that is applied to routine gray-scale echocardiographic images, which is not limited by Doppler angle.

Suffoletto MS et al 2006 Circulation
Sensitivity 89%
Specificity 83%
(10) 3D Echocardiography

- The advantage of real-time 3-dimensional echocardiography is that it allows for a comparison of synchrony between of the segments of the LV together in the same cardiac cycle.
- **Dyssynchrony index** from the dispersion of time to minimum regional volume.

Kapetanakis et al 2005 Circulation

*JASE (2008;21:191-213) Modified*
However,

It is important to point out that most clinical studies were observational series from single-center, which had reported significant inter- and intraobserver variability (up to almost 10%).

Therefore, these results may not be reproducible in other centers, in different patient populations, or with different imaging experiences or capabilities.
Results of the Predictors of Response to CRT (PROSPECT) Trial

Eugene S. Chung, MD; Angel R. Leon, MD; Luigi Tavazzi, MD; Jing-Ping Sun, MD; Petros Nihoyannopoulos, MD; John Merlino, MD; William T. Abraham, MD; Stefano Ghio, MD; Christophe Leclercq, MD; Jeroen J. Bax, MD; Cheuk-Man Yu, MD, FRCP; John Gorcsan III, MD; Martin St John Sutton, FRCP; Johan De Sutter, MD, PhD; Jaime Murillo, MD

Background—Data from single-center studies suggest that echocardiographic parameters of mechanical dyssynchrony may improve patient selection for cardiac resynchronization therapy (CRT). In a prospective, multicenter setting, the Predictors of Response to CRT (PROSPECT) study tested the performance of these parameters to predict CRT response.

Methods and Results—Fifty-three centers in Europe, Hong Kong, and the United States enrolled 498 patients with standard CRT indications (New York Heart Association class III or IV heart failure, left ventricular ejection fraction ≤35%, QRS ≥130 ms, stable medical regimen). Twelve echocardiographic parameters of dyssynchrony, based on both conventional and tissue Doppler–based methods, were evaluated after site training in acquisition methods and blinded core laboratory analysis. Indicators of positive CRT response were improved clinical composite score and ≥15% reduction in left ventricular end-systolic volume at 6 months. Clinical composite score was improved in 69% of 426 patients, whereas left ventricular end-systolic volume decreased ≥15% in 56% of 286 patients with paired data. The ability of the 12 echocardiographic parameters to predict clinical composite score response varied widely, with sensitivity ranging from 6% to 74% and specificity ranging from 35% to 91%; for predicting left ventricular end-systolic volume response, sensitivity ranged from 9% to 77% and specificity from 31% to 93%. For all the parameters, the area under the receiver-operating characteristics curve for positive clinical or volume response to CRT was ≤0.62. There was large variability in the analysis of the dyssynchrony parameters.

Conclusion—Given the modest sensitivity and specificity in this multicenter setting despite training and central analysis, no single echocardiographic measure of dyssynchrony may be recommended to improve patient selection for CRT beyond current guidelines. Efforts aimed at reducing variability arising from technical and interpretative factors may improve the predictive power of these echocardiographic parameters in a broad clinical setting. (Circulation. 2008;117:2608-2616.)

Results of the Predictors of Response to CRT (PROSPECT) Trial

Eugene S. Chung, MD; Angel R. Leon, MD; Luigi Tavazzi, MD; Jing-Ping Sun, MD; Petros Nihoyannopoulos, MD; John Merlino, MD; William T. Abraham, MD; Stefano Ghio, MD; Christophe Leclercq, MD; Jeroen J. Bax, MD; Cheuk-Man Yu, MD, FRCP; John Gorcsan III, MD; Martin St John Sutton, FRCP; Johan De Sutter, MD, PhD; Jaime Murillo, MD

Background—Data from single-center studies suggest that echocardiographic parameters of mechanical dyssynchrony may improve patient selection for cardiac resynchronization therapy (CRT). In a prospective, multicenter setting, the Predictors of Response to CRT (PROSPECT) study tested the performance of these parameters to predict CRT response.

Methods and Results—Fifty-three centers in Europe, Hong Kong, and the United States enrolled 498 patients with standard CRT indications (New York Heart Association class III or IV heart failure, left ventricular ejection fraction ≤35%, QRS ≥130 ms, stable medical regimen). Twelve echocardiographic parameters of dyssynchrony, based on both conventional and tissue Doppler–based methods, were evaluated after site training in acquisition methods and blinded core laboratory analysis. Indicators of positive CRT response were improved clinical composite score and ≥15% reduction in left ventricular end-systolic volume at 6 months. Clinical composite score was improved in 69% of 426 patients, whereas left ventricular end-systolic volume decreased ≥15% in 56% of 286 patients with paired data. The ability of the 12 echocardiographic parameters to predict clinical composite score response varied widely, with sensitivity ranging from 6% to 74% and specificity ranging from 35% to 91%; for predicting left ventricular end-systolic volume response, sensitivity ranged from 9% to 77% and specificity from 31% to 93%. For all the parameters, the area under the receiver-operating characteristics curve for positive clinical or volume response to CRT was ≤0.62. There was large variability in the analysis of the dyssynchrony parameters.

Conclusion—Given the modest sensitivity and specificity in this multicenter setting despite training and central analysis, no single echocardiographic measure of dyssynchrony may be recommended for patient selection for CRT. Interpretative factors may improve the predictive power of these echocardiographic parameters in a broad clinical setting. (Circulation. 2008;117:2608-2616.)
• Patient selection: EF>35% in 20.5% of patients
• Technical issue: high interobserver variability
• Pathophysiologic issue: scar tissue, lead position
Dyssynchrony Indices To Predict Response to Cardiac Resynchronization Therapy
A Comprehensive Prospective Single-Center Study

Chinami Miyazaki, MD*; Margaret M. Redfield, MD*; Brian D. Powell, MD; Grace M. Lin, MD; Regina M. Herges, BS; David O. Hodge, MS; Lyle J. Olson, MD; David L. Hayes, MD; Raul E. Espinosa, MD; Robert F. Rea, MD; Charles J. Bruce, MD; Susan M. Nelson, LPN; Fletcher A. Miller, MD; Jae K. Oh, MD

Background—Whether mechanical dyssynchrony indices predict reverse remodeling (RR) or clinical response to cardiac resynchronization therapy (CRT) remains controversial. This prospective study evaluated whether echocardiographic dyssynchrony indices predict RR or clinical response after CRT.

Methods and Results—Of 184 patients with heart failure with anticipated CRT who were prospectively enrolled, 131 with wide QRS and left ventricular ejection fraction <35% had 6-month follow-up after CRT implantation. Fourteen dyssynchrony indices (feasibility) by M-mode (94%), tissue velocity (96%), tissue Doppler strain (92%), 2D speckle strain (65% to 86%), 3D echocardiography (79%), and timing intervals (98%) were evaluated. RR (end-systolic volume reduction ≥15%) occurred in 55% and more frequently in patients without (71%) than in patients with (42%) ischemic cardiomyopathy ($P=0.002$). Overall, only M-mode, tissue Doppler strain, and total isovolumic time had a receiver operating characteristic area under the curve (AUC) greater than the line of no information, but none of these were strongly predictive of RR (AUC, 0.63 to 0.71). In nonischemic cardiomyopathy, no dyssynchrony index predicted RR. In ischemic cardiomyopathy, M-mode (AUC, 0.67), tissue Doppler strain (AUC, 0.79), and isovolumic time (AUC, 0.76) -derived indices predicted RR ($P<0.05$ for all), although the incremental value was modest. No indices predicted clinical response assessed by Minnesota Living with Heart Failure Questionnaire, 6-minute walk distance, and peak oxygen consumption.

Conclusions—These findings are consistent with the Predictors of Response to CRT study and do not support use of these dyssynchrony indices to guide use of CRT. (Circ Heart Fail. 2010;3:565-573.)
RR after CRT 6 months (all patients)

55% RR
Role of Echo

No index for prediction of RR

AUC
TD strain  0.79
IVT        0.76
M-mode     0.67
This prospective single-center study confirmed the PROSPECT trial’s conclusion and does not support a routine use of any echocardiographic dyssynchrony index to select patients for CRT.

Future investigations should focus on further characterizing the clinical and laboratory features of the patients who do not respond to CRT.
Summary

- CHF (NYHA III-IV)
- EF<35%
- QRS widening
- Dyssynchrony Echo
- CT (normal anatomy)
- MRI (no scar)
- High CRT response
